Claude Code

I have a JSONL dataset where each line contains a 'chunk' field with factual text. Please help me construct a pipeline to first generate multi-hop QA pairs for each chunk, then score the quality of the generated QAs, and finally filter out low-quality records (score < 3).

On it — task (QA generation + quality scoring + filtering). Let me pull the operator details for Text2QASampleEvaluator and GeneralFilter via MCP to get exact field bindings before designing the chain.

- ✓ Got operator detail: Text2QASampleEvaluator
- ✓ Got operator detail: GeneralFilter
- ✓ Got operator detail: PandasOperator

These operator contracts reveal the core challenge: Text2QASampleEvaluator needs scalar input_question_key / input_answer_key columns — it cannot consume the nested qa_pairs list directly. So I must explode qa_pairs into per-QA rows
